General Medical Information

Hypertension (high blood pressure) is a chronic medical condition in which the force of the blood against the artery walls is consistently too high. It is often called a “silent killer” because it may not present noticeable symptoms but can lead to serious complications such as heart disease, stroke, and kidney failure if left untreated. Normal blood pressure is typically around 120/80 mmHg. Readings above 140/90 mmHg are generally considered hypertensive.

Diabetes Mellitus is a metabolic disorder characterized by high blood sugar levels over a prolonged period. There are two primary types: Type 1 diabetes, where the body does not produce insulin, and Type 2 diabetes, where the body becomes resistant to insulin. Common symptoms include increased thirst, frequent urination, fatigue, and blurred vision. Long-term complications include cardiovascular disease, nerve damage, and kidney damage.

Cardiovascular Diseases

Coronary Artery Disease (CAD) occurs when the coronary arteries that supply blood to the heart muscle become narrowed or blocked due to plaque buildup. Symptoms may include chest pain (angina), shortness of breath, and fatigue. Risk factors include smoking, high cholesterol, obesity, and lack of physical activity.

Heart failure is a condition in which the heart is unable to pump sufficient blood to meet the body's needs. Symptoms include swelling in the legs, fatigue, and shortness of breath. Treatment often includes medications such as ACE inhibitors, beta-blockers, and lifestyle changes.

Respiratory Diseases

Asthma is a chronic inflammatory disease of the airways that causes episodes of wheezing, breathlessness, chest tightness, and coughing. It can be triggered by allergens, exercise, cold air, or stress. Treatment typically involves inhalers such as bronchodilators and corticosteroids.

Chronic Obstructive Pulmonary Disease (COPD) is a progressive lung disease that includes emphysema and chronic bronchitis. It is commonly caused by long-term exposure to irritants such as cigarette smoke. Symptoms include chronic cough, mucus production, and difficulty breathing.

Neurological Disorders

Alzheimer's disease is a progressive neurological disorder that leads to memory loss, cognitive decline, and behavioral changes. It primarily affects older adults and currently has no cure, though medications can help manage symptoms.

Parkinson's disease is a disorder of the central nervous system that affects movement. Symptoms include tremors, stiffness, and difficulty with balance and coordination. It is caused by the loss of dopamine-producing neurons in the brain.

Common Medications

Paracetamol (Acetaminophen) is commonly used to treat mild to moderate pain and fever. It is generally safe when used at recommended doses but can cause liver damage if overdosed.

Ibuprofen is a nonsteroidal anti-inflammatory drug (NSAID) used to reduce pain, inflammation, and fever. Long-term use may cause gastrointestinal issues or kidney problems.

Insulin is a hormone used in the treatment of diabetes to help regulate blood sugar levels. It can be administered via injections or insulin pumps.
